

## 11 Writing Assignment Due Thursday, April 23

Choose a function  $f(x)$ . A function  $g(x)$  is called a *right inverse* to  $f$  if

$$f(g(x)) = x.$$

In other words, if you (i) begin with a number  $x$ , (ii) apply  $g$  to get a new number called  $g(x)$ , and (iii) apply  $f$  to  $g(x)$ , you get back the number  $x$  you began with.

Here are some examples:

1. If  $f(x) = e^x$ , a right inverse  $g$  is given by  $\ln(x)$ .
2. If  $f(x) = \cos(x)$ , a right inverse  $g$  is given by  $\arccos(x)$ .
3. If  $f(x) = \tan(x)$ , a right inverse  $g$  is given by  $\arctan(x)$ .
4. If  $f(x) = x$ , a right inverse  $g$  is given by  $x$ .
5. If  $f(x) = x^3$ , a right inverse  $g$  is given by  $x^{1/3}$ .

Note that the domain of a right inverse is often determined by the range of  $f$ .

For each of the above examples, try drawing the graph of  $f$ , and the graph of a right inverse  $g$  to  $f$ . How are the two graphs related? For example, draw the line  $y = x$  with the graphs of  $f$  and  $g$ . It should seem like the graph of  $g$  is obtained by “reflecting” the graph of  $f$  along the line  $y = x$ .

**Prompt.** Why should it be true that a graph of a right inverse is obtained by reflecting the graph of  $f$  along the line  $y = x$ ?

**Format.** See online. Only PDF uploads are accepted on Canvas.
